

Practical :- 2

o Hello world, Components. JSX

Step : 1 : Import React

- o Create a file named MyComponent.js in a src directory and import the React at the top of the file.js

```
import React from "react" ;
```

Step : 2 : Define the Component

- o Create a functional Component by writing a JavaScript function. Components in React are essentially JavaScript function that return JSX (JavaScript XML) to describe the Component's structure and appearance.

```
const MyComponent = () => {
```

```
  return (
```

```
    <div>
```

```
      <h1> Hello this my First React Component </h1>
```

```
    </div>
```

```
  );
```

```
};
```

Step : 3 : Export the Component

- Export your component so that it can be used in other parts of your application.

Export default MyComponent;

Step : 4 : Using the Component

- In another part of your application, you can import and use your component like this. we will import our new component in app.js file.

```
import './App.css';
import MyComponent from './MyComponent';
function App() {
  return (
    <div className="App">
      <MyComponent />
    </div>
  );
}
```

Export default App;

- Now, when you render App, it will include your MyComponent displaying "Hello this my first React Component" on your webpage. This is the foundational process of creating and using components in React.
